

Figure 2 | Among sorted germinal-centre B cells, clones differ along a continuum

Model-antigen immunisation, where affinity and selection are controlled and the cells were sorted by what they had been doing.

a

Model antigens: what the cell had been doing is measured, not inferred

b

c

Clones sit on a continuum: no split between groups of clones was significant in either experiment that could be tested.

d

dashed outline: the same label shuffled among clones of the same mouse; grey: not significant

e

0 = a clone's cells in one compartment say nothing about its cells in the other; 1 = they are as alike as two samples of the same thing

f

correlation within a clone between mutation and expression distance

Each point is one clone. Which sub-lineage a cell belongs to does not predict what it is doing. The two lower experiments would have detected a correlation of 0.05-0.08; the two smaller ones cannot exclude a modest effect.

g

mutations from the unmutated ancestor, difference within a clone

An independent check that uses only the receptor sequences: cells further from the unmutated ancestor arose later in their clone's history. Taken within clones.
