

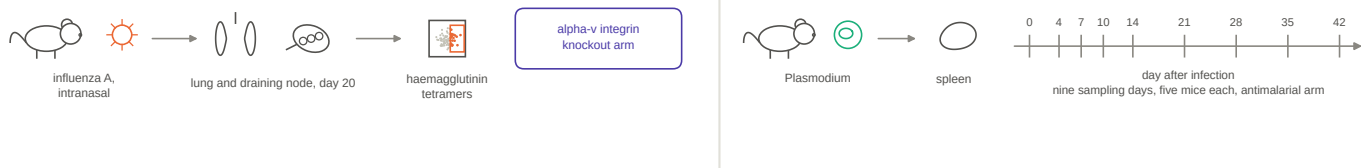

Figure 3 | The same questions under live infection

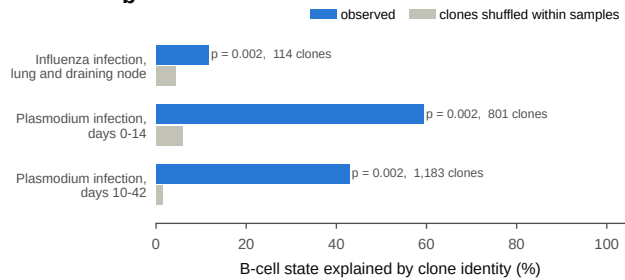

Influenza A in mouse lung and draining node, and a Plasmodium infection followed from day 0 to day 42.

a

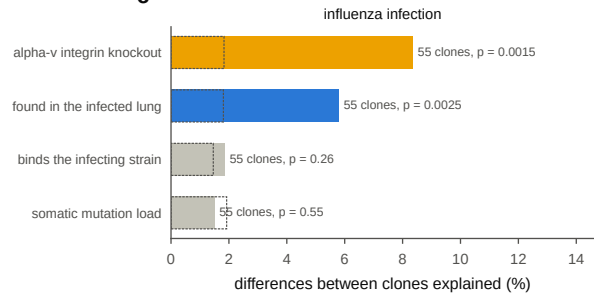

Live infection: antigen for weeks, many germinal centres at once

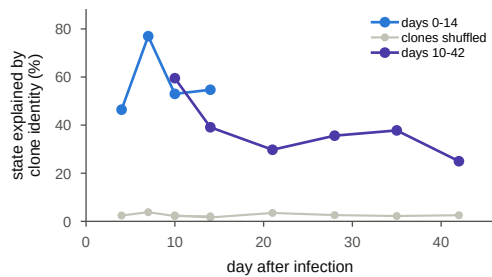

b

c

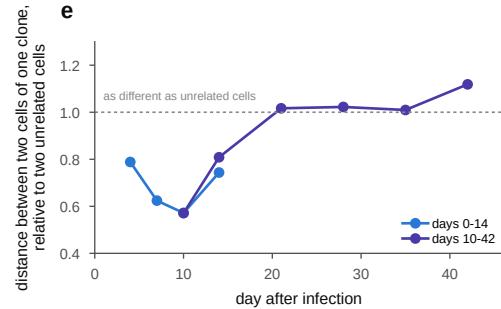

d

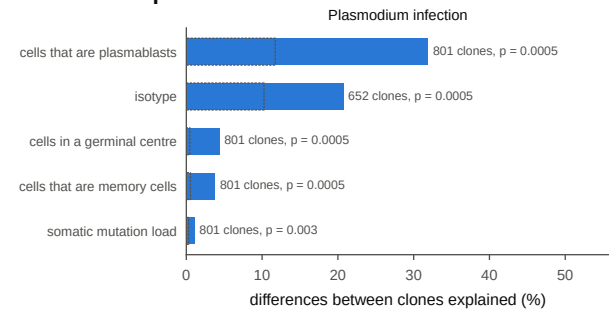

Two experiments, each with five mice per day. Clonal structure is strongest in the first week and is diluted as the response broadens.

e

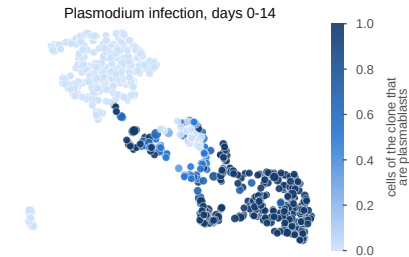

A clone starts as a tight group of cells and ends as diverse as the repertoire around it - the internal diversification the original study describes, put on a scale.

f

g

Clones that sent cells to the plasmablast fate sit apart from those that did not, without being separate groups.
