

Supplementary Figure 3 | The model-antigen germinal centre in detail

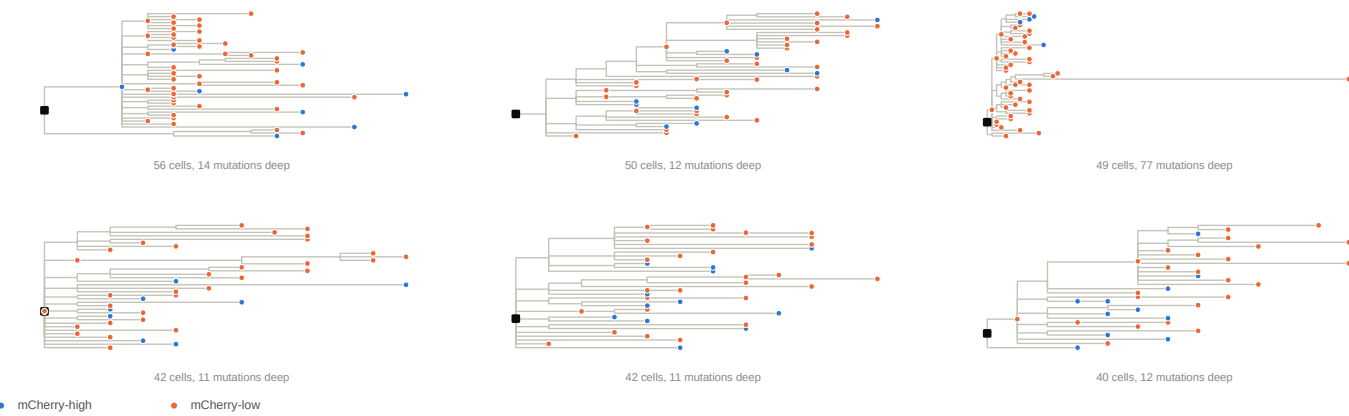

Every measured label of every experiment behind Figure 2, and the lineage trees that check it against the receptor sequences alone.

a What explains the differences between germinal-centre clones, experiment by experiment

Sequence-level selection is the excess of amino-acid-changing mutations over what that clone's own germline gives by chance. It is largely unrelated to the clone's transcriptional behaviour, so the two measurements are not restatements of each other.

d Lineage trees of germinal-centre clones, NP-OVA division reporter

Each tree is one clone, rooted at its unmutated ancestor (square); each dot is a cell, coloured by its division gate. Cells of both gates are scattered through the same trees, which is the picture behind the null result in Figure 2f.
