

Figure 3 | Clone-state variation across Plasmodium infection

Receptor-defined families resolve captured state mixtures and variation within a shared cell annotation.

A Two infection cohorts with different sampling designs

PcAS infection

Terminal spleen sampling

Different mice at each date

Experiment 1 · early infection

Experiment 2 · late infection + treatment

B Early infection: output-biased family profiles

801 reliable clones; clone UMAP

D Captured cell states in later infection

72,359 cells; cell UMAP

C Later infection: GC, PB and memory-associated family states

1,183 reliable clones; clone UMAP
Neighbourhoods reflect captured profile similarity; region labels describe state enrichment.

E Pure-PB families retain cycling-state variation

329 pure-PB families; RNA-derived description.
Within-mouse direction: 10/10 negative (≥5 families/mouse; median p=-0.60).

F GC-enriched families are captured at late infection timepoints

Each dot is one mouse; lines join group medians.
GC-enriched: ≥50% GC cells. Three mice/arm/day; independent terminal samples, not tracked clones.
