

Figure 4 | Lineage barcodes connect early clone states to later observations

LARRY mouse haematopoiesis | GSE140802 | future observations are excluded from the prediction features.

A One lineage barcode, separately observed at each sampling day

130,887 input cells; 49,302 barcode-labelled cells; 172 prediction-eligible barcodes.

B LARRY authors' cell SPRING map

Undifferentiated
Monocyte
Neutrophil
Baso
Mast
Meg
Lymphoid
Eos
Ccr7_DC
pDC
Erythroid

Author SPRING coordinates; 40,000 cells displayed.
All eleven author annotations are retained.

C Threadfin kernel: clone-by-day profiles

7,575 clone-day profiles; colour = dominant captured state.
Lines join the same barcode; labels denote day, not inferred pseudotime.

D Do early profiles anticipate later neutrophil capture?

E Early-state prediction with RNA baselines

D-E: ≥ 2 day-2 and ≥ 4 day-6 cells per barcode. Three repeated five-fold splits; repeats are not biological replicates.
Later RNA-defined state fractions validate temporal association; they do not measure a clone's complete developmental potential.
