

Supplementary Figure 6 | Binding-label provenance and donor-level GC mutation trends

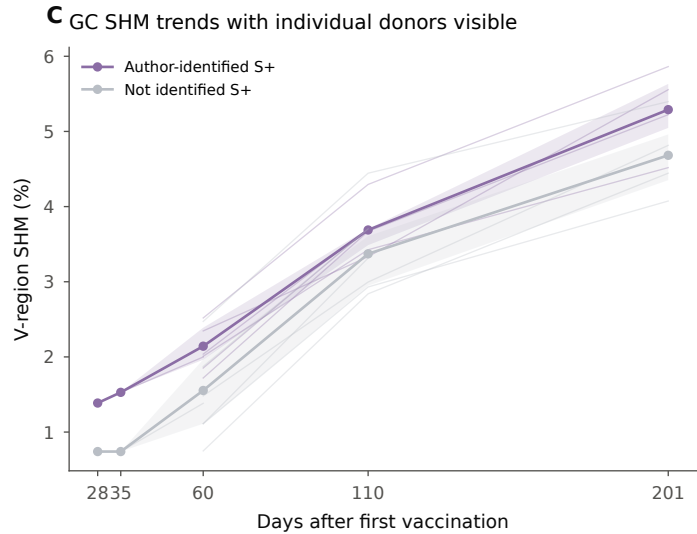

Sequence identity, author clone annotation and measured SHM are audited separately.

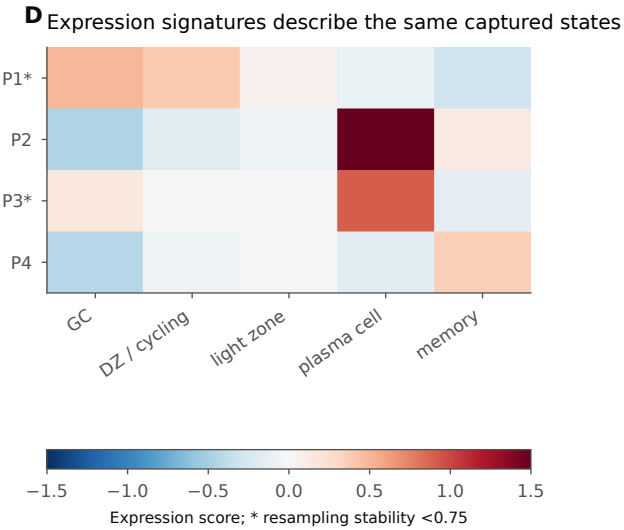

623 author clones are split; each Threadfin family maps to one author clone.
A propagated binding label is not a newly measured biological replicate.

One dot per donor/programme; family-level labels.
FALSE is not a uniformly assayed negative.

Equal-donor mean of family-SHM medians; shading = donor IQR.
Donors at each date: 1, 1, 8, 6, 4. Different families can contribute at different dates.

Modules reuse profile-building expression.
Agreement is descriptive, not independent validation.
