

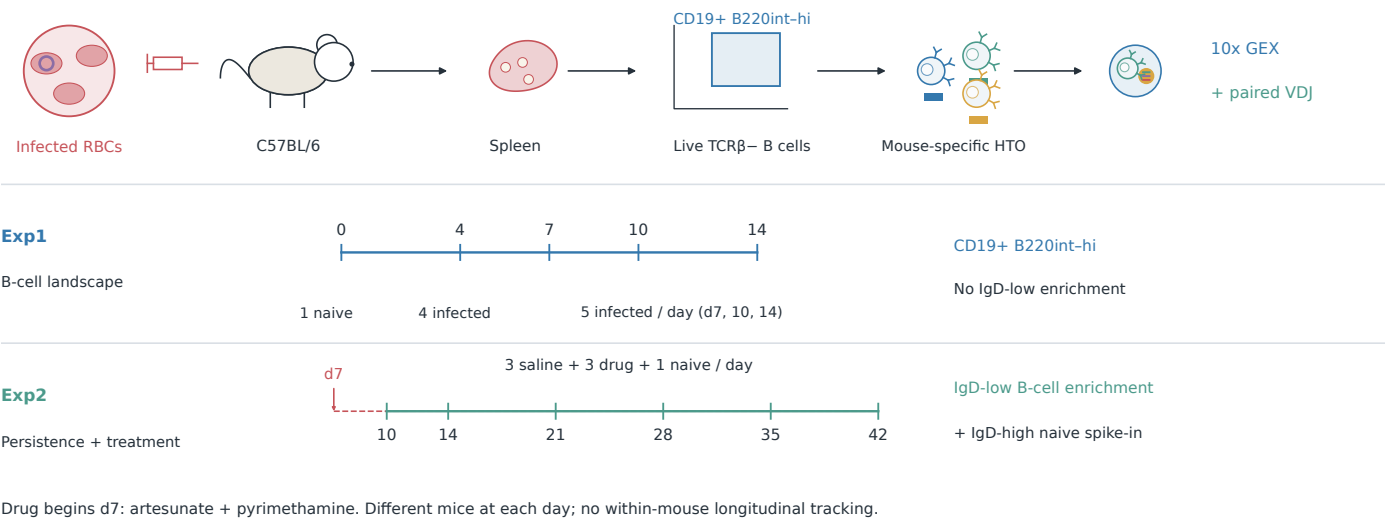

Figure 3 | Clonal co-occupancy of GC and output-like states in Plasmodium

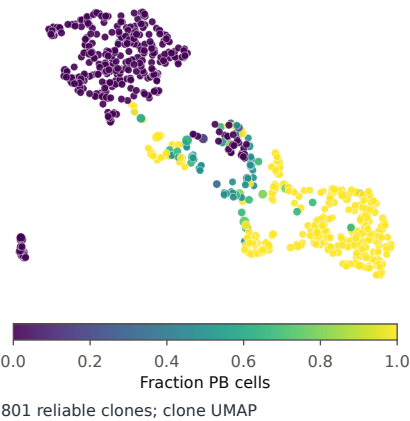

Same-mouse clone membership tests shared ancestry; independent terminal samples define the time course.

A Infection, sample preparation and treatment are represented explicitly

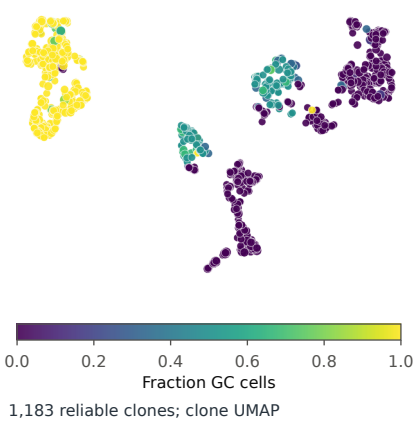

PcAS blood-stage infection → terminal spleen sampling → paired cell and receptor records

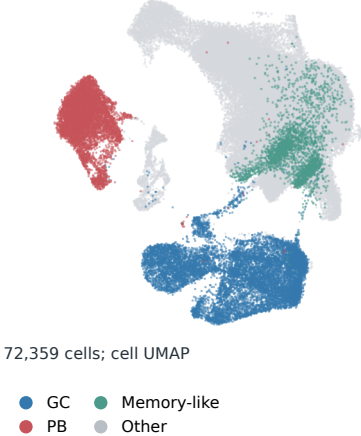

B Early infection: PB-biased clone profiles

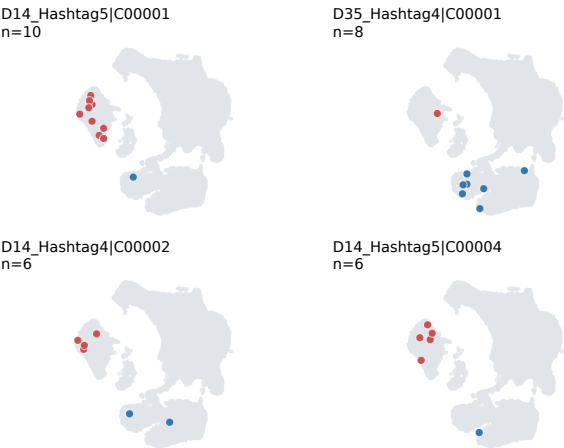

C Later infection: GC-biased clone profiles

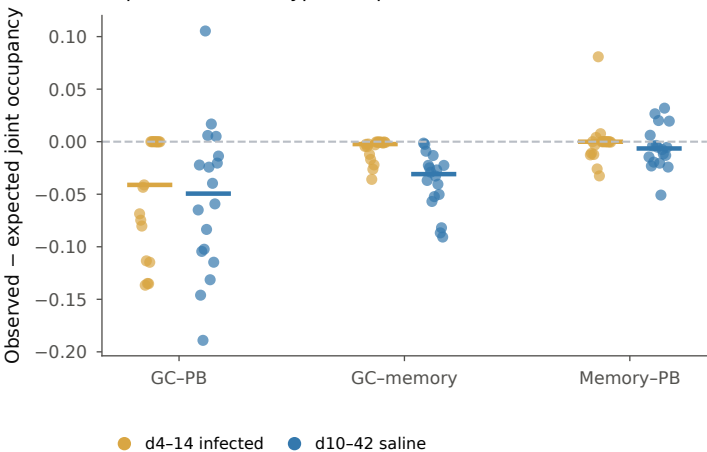

D Cell states underlying the later clone map

E Co-observed cells of individual GC-PB clones

F Is shared occupancy more than expected from isotype composition?

Each inset shows one BCR-defined clone on the same cell UMAP.

Fixed denominator: all clones with ≥ 2 captured cells. Null preserves mouse, clone size and per-cell isotype.
