

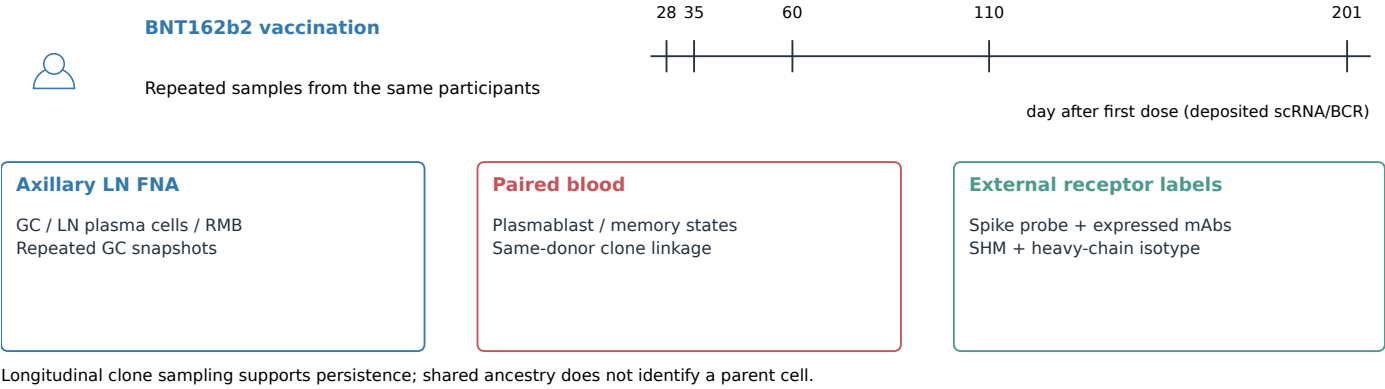

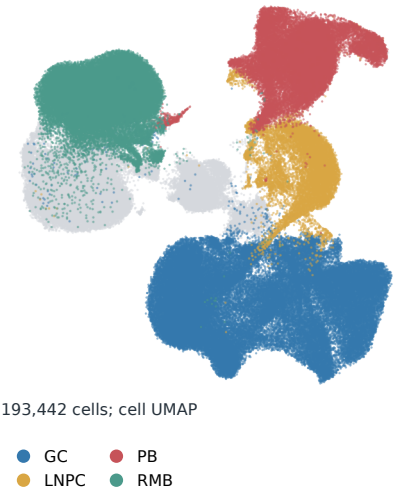

Figure 4 | Testing GC clone persistence and compartment bias in humans

Repeat sampling, author-identified binding labels and mutation history provide different measurements.

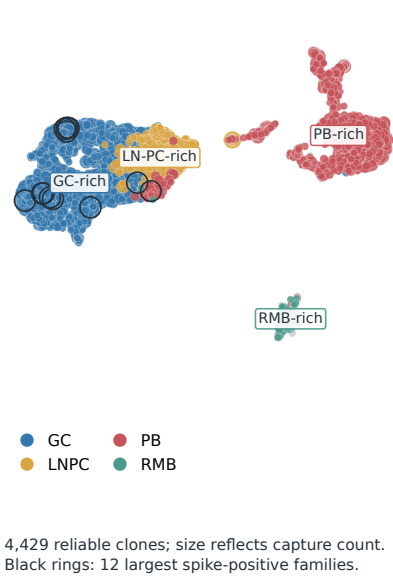

A Repeated lymph-node aspiration and blood sampling after mRNA vaccination

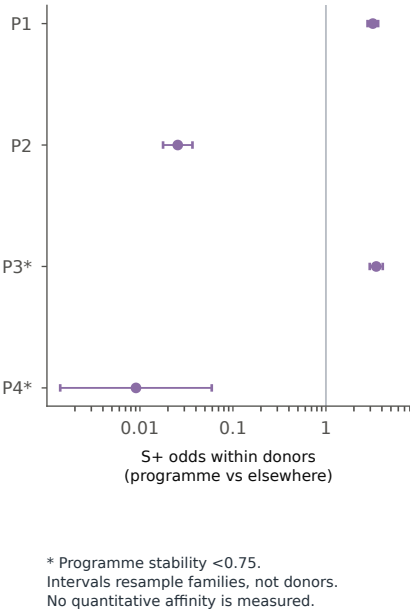

B GC and output compartments

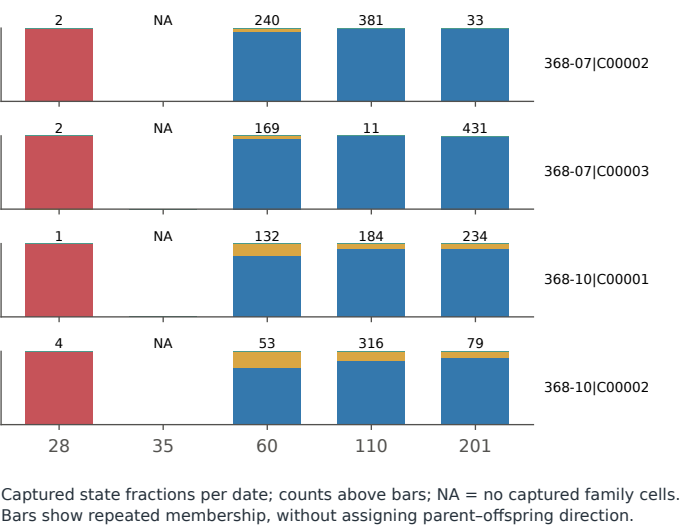

C Clone families by captured state

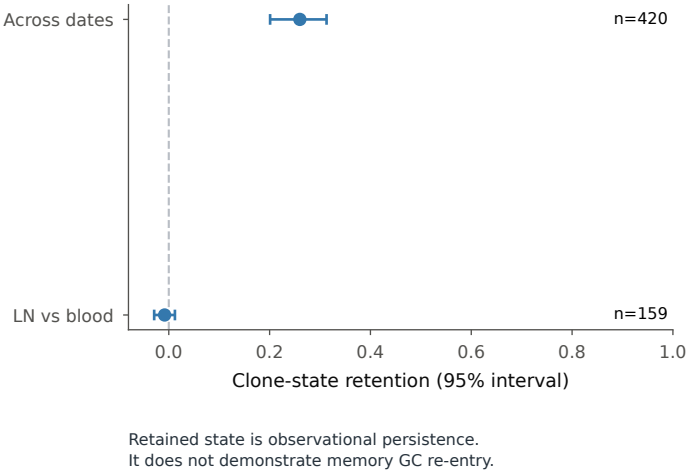

D Are expression programmes enriched for S+ families?

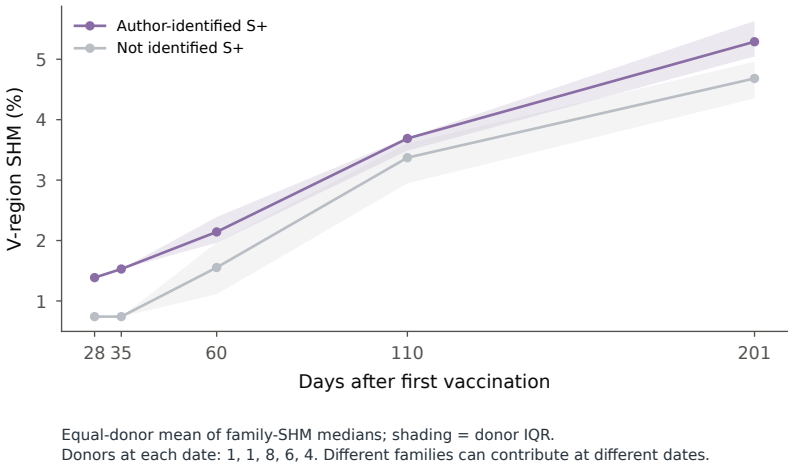

E GC-containing clones sampled repeatedly

F What does a clone retain?

G SHM of captured GC families: binding labels are compared explicitly

H What does this comparison measure?

Threadfin: sequence-defined families
RNA: captured family state profiles
S+: authors' binding classification
SHM: V-region mutation frequency

These are associated measurements.
SHM and binary binding are not affinity.
Early dates: one nonpooled donor.
