

Figure 5 | What receptor-defined families add to the captured expression landscape

Twelve dataset analyses contribute different evidence; expression resemblance alone does not validate fate.

A Biological anchors determine the question each model can answer

B Do related cells resemble each other beyond the library baseline?

500 within-library shuffles preserve clone sizes and library composition.
Short black segment: shuffled mean to 95th percentile. NP PC/GC: p = 0.224.

C Captured profiles

Expanded	Reliable
373	69
1,414	381
113	3
801	801
1,183	1,183
8,435	4,429
9,783	9,783
1,997	1,997
114	55
6,923	2,314
670	75
83	83

Expanded: ≥2 captured cells.
Reliable: profile reliability ≥0.5.
Small profiles can restrict interpretation.

D Which expression programmes are more similar within families?

E Read the evidence at its experimental resolution

- Reporter → recent divisions
- Same mouse → state co-occupancy
- Same donor, repeat dates → persistence
- Pure gates + H/L → receptor identity

No panel measures future fate,
GC re-entry or binding affinity.
