

Supplementary Figure 3 | Plasmodium sharing controls and candidate selection

Each dot is one mouse; 3 mice per infected arm/day.
Sparse GC-bearing clones limit treatment interpretation.

D What the experiment can and cannot establish

- Supported
- Same-mouse clone membership
 - GC / output state occupancy
 - Day- and treatment-associated differences
- Requires additional evidence
- Memory re-entry into GC
 - Parent-offspring direction
 - Future PC or memory fate
 - Antigen affinity / functional protection

E Predeclared candidate rule

Examples require both displayed states within one mouse and one time point, then rank by captured size.
Exact IGH and paired-light controls test whether sharing survives conservative sequence matching.
The supplement reports clone-size sensitivity and conditional nulls; illustrative examples are not independent validation.
