

Supplementary Figure 8 | Historical Top2a display and current model-antigen GC state evidence

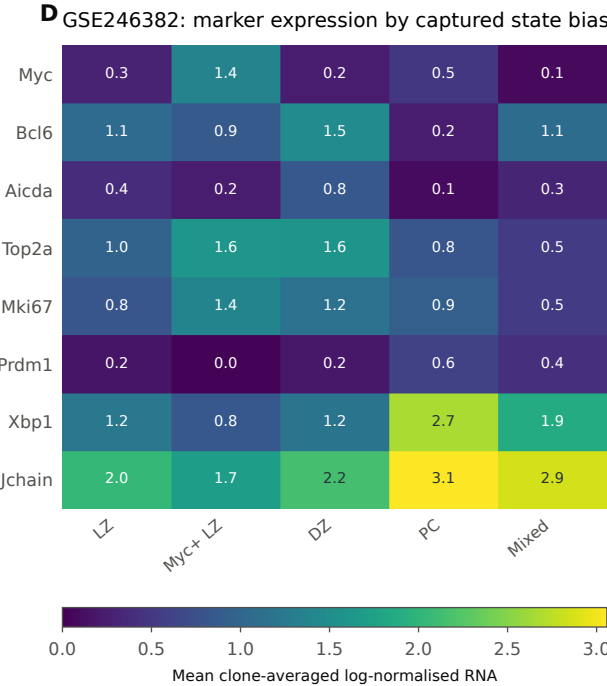

A is an archived output; B-D are audited real-data GSE246382 views with measured gates and descriptive RNA.

Notebook cell 33 output; cohort and sampling day unresolved.

New clone coordinates, same 49 families as Figure 2B.
Myc is averaged over captured members of each family.

E Interpret the model-antigen GC nodes within their evidence

New analysis: receptor-excluded PCA → clone centroids → precomputed-distance UMAP; continuous preset, seed 123.
Myc+ LZ-biased families have higher Myc RNA; PC-biased families have higher plasma-cell expression modules.
Colour indicates captured compartment bias, not a learned fate class. Tied predominant gates are labelled mixed.
The primary Leiden graph gives one partition; its separated state biases are not validated discrete programmes.
A is a separate historical display. B-D do not assign a differentiation direction or extend GC interpretation to non-GC.
