

Figure 5 | Exact paired TCRs track changes in captured clone states

NSCLC blood CD8 T cells | GSE266219 | ten public patients; no response-group assignments inferred.

A Retain longitudinal identity without treating distribution shifts as differentiation

124,534 cells with one TRA and one TRB; 10,428 expanded clone-cycle profiles.

B Cell-level expression context

30,000 cells displayed
Same RNA modules used in C.

C Clone-state continuum

10,428 reliable clone-cycle profiles; size = captured cells.

D Does exact clone identity retain state information?

One dot per patient; median across observed intervals.
Below 1: closer than a different matched clone.

E Observed state changes vary across patients

One point per patient/interval; ≥ 4 cells per clone/date.
RNA scores describe expression; they are not efficacy readouts.

D: 200 target permutations within patient, interval and capture-count bin; the same clone pairs are used for all three methods.
Expansion, contraction and migration can all change blood clone composition. Clinical-response claims require an audited outcome mapping.
